

## Task 1

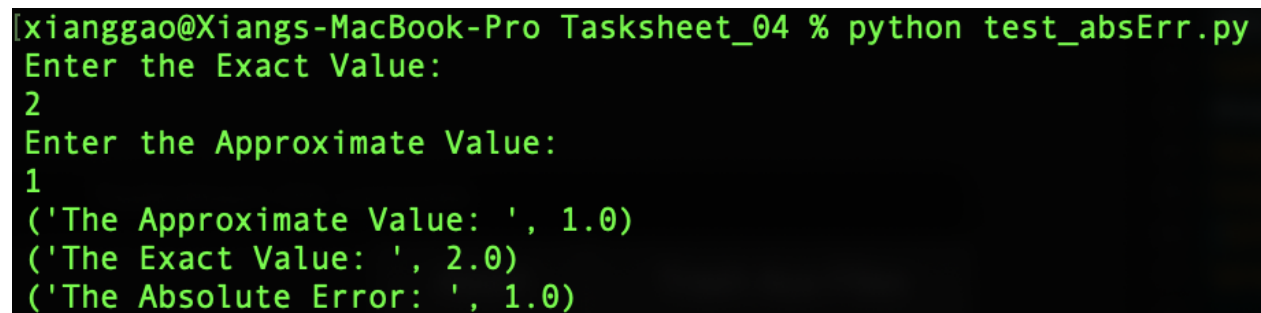

I have created a `absErr.py` file and `relErr.py` file each with their own testing file. I have documented both .py files in my Software Manual. In addition, I have added the error files to my shared library. The routine for the absolute error is provided below:

```
1 import numpy as np
2
3 def absErr(exVal, apprVal):
4     absErr = np.abs(exVal - apprVal)
5     print('The Approximate Value: ', apprVal)
6     print('The Exact Value: ', exVal)
7     print('The Absolute Error: ', absErr)
```

With the following code for testing:

```
1 import numpy as np
2 from absErr import absErr
3
4 exVal = input('Enter the Exact Value:\n')
5
6 apprVal = input('Enter the Approximate Value:\n')
7
8 absErr(np.float32(exVal), np.float32(apprVal))
```

And the following output:

```
[xianggao@Xiangs-MacBook-Pro Tasksheet_04 % python test_absErr.py
Enter the Exact Value:
2
Enter the Approximate Value:
1
('The Approximate Value: ', 1.0)
('The Exact Value: ', 2.0)
('The Absolute Error: ', 1.0)
```

Figure 1. Machine Epsilon Single Precision Output:

The routine for relative error is provided below:

```
1 import numpy as np
2
3 def relErr(exVal, apprVal):
4     relErr = (np.abs(exVal - apprVal))/exVal
5     print('The Approximate Value: ', apprVal)
6     print('The Exact Value: ', exVal)
7     print('The Absolute Error: ', relErr)
```

With the following code for testing:

```
1 import numpy as np
2 from relErr import relErr
3
4 exVal = input('Enter the Exact Value:\n')
5
6 apprVal = input('Enter the Approximate Value:\n')
7
8 relErr(np.float32(exVal), np.float32(apprVal))
```

And the following output:

```
[xianggao@Xiangs-MacBook-Pro Tasksheet_04 % python test_relErr.py
Enter the Exact Value:
2
Enter the Approximate Value:
1
('The Approximate Value: ', 1.0)
('The Exact Value: ', 2.0)
('The Absolute Error: ', 0.5)
```

Figure 2. Machine Epsilon Double Precision Output.

## Task 2

I have created a graphics routine as shown in the following:

```
1 import matplotlib.pyplot as plt
2 import numpy as np
3
4 # Initialize two arrays to store the input data in
5 # -----
6 xpts=[]
7 ypts=[]
8
9 # Identify number of sub-plots from the user
10 # -----
11 plot_num = input('Enter number of expressions you want to plot:\n')
12
13 # Request from user the endpoints of the interval that defines the graphical domain
14 # -----
15 xmin = input('Enter left endpoint of an interval:\n')
16 xmin = float(xmin)
17 xmax = input('Enter right endpoint of an interval:\n')
18 xmax = float(xmax)
19
20 # Request from user the number of points for graphing the expression given
21 # -----
22 nvals = input('Enter the number of points for graphing the expression:\n')
23 nvals = float(nvals)
24 delx = (xmax - xmin) / float(nvals)
25 i = 0
26 while i <= nvals:
27     x = xmin + float(i) * delx
28     xpts.append(x)
29     i += 1
30
31 # Graphics for the input given
32 # -----
33 plt.xlim(xmin, xmax)
34
35 # Loop over the number of expressions specified
36 # -----
37 expression = input('Enter the next expression (include np.) for f(x):\n')
38
39 # Loop over the points, evaluating the expression
40 # -----
41 i = 0
42 while i <= nvals:
43     x = xpts[i]
44     ypts.append(eval(expression))
45     i += 1
46
47 # Plot the data using matplotlib.pyplot
```

```

48 # -----
49 plt.plot(xpts, ypts, label=expression)
50
51 # Hardcoding axes labels for the 2D plot
52 # -----
53 plt.xlabel('x-axis')
54 plt.ylabel('y-axis')
55
56 # Create a legend for the plot
57 # -----
58 plt.legend()
59
60 # Show the plot of the data
61 # -----
62 plt.show()

```

Where I wanted to draw the **topologist's sine wave**, so I give it the following input

```

Enter number of expressions you want to plot:
1
Enter left endpoint of an interval:
0.001
Enter right endpoint of an interval:
1
Enter the number of points for graphing the expression:
200
Enter the next expression (include np.) for f(x):|
np.sin(np.power(x,-1))

```

**Figure 3.** Input for the Graphics Routine.

And it produced the following output

**Figure 4.** Output for the Graphics Routine.

## Task 3

The routine is given by the following:

```

1 import numpy as np
2
3 def f(x):
4     return x * x * x + x * x - 1
5
6 # Re-writing f(x)=0 to x = g(x)
7 def g(x):
8     return 1 / np.sqrt(1 + x)
9
10 def fixedPointIteration(x0, e, N):
11     print('\n\n*** FIXED POINT ITERATION ***')
12     step = 1
13     flag = 1
14     condition = True
15     while condition:
16         x1 = g(x0)
17         print('Iteration-%d, x1 = %0.6f and f(x1) = %0.6f' % (step, x1, f(x1)))
18         x0 = x1
19         step = step + 1
20         if step > N:
21             flag = 0
22             break
23         condition = abs(f(x1)) > e
24     if flag == 1:
25         print('\nRequired root is: %0.8f' % x1)
26     else:
27         print('\nNot Convergent.')
28
29 # Input Section
30 x0 = float(input('Guess the root: '))
31 e = float(input('Tolerable error: '))
32 N = int(input('Maximum steps: '))
33
34 fixedPointIteration(x0, e, N)

```

And the result is given by:

```

Guess the root: 2
Tolerable error: 0.00001
Maximum steps: 10

*** FIXED POINT ITERATION ***
Iteration-1, x1 = 0.577350 and f(x1) = -0.474217
Iteration-2, x1 = 0.796225 and f(x1) = 0.138761
Iteration-3, x1 = 0.746139 and f(x1) = -0.027884
Iteration-4, x1 = 0.756764 and f(x1) = 0.006085
Iteration-5, x1 = 0.754472 and f(x1) = -0.001305
Iteration-6, x1 = 0.754965 and f(x1) = 0.000281
Iteration-7, x1 = 0.754859 and f(x1) = -0.000060
Iteration-8, x1 = 0.754882 and f(x1) = 0.000013
Iteration-9, x1 = 0.754877 and f(x1) = -0.000003

Required root is: 0.75487680

```

Figure 5. Fixed point method for an example function.

## Task 4

Use the code for the previous task, I got the following result.

```

Guess the root: 2
Tolerable error: 0.5
Maximum steps: 20

*** FIXED POINT ITERATION ***
Iteration-1, x1 = 0.000086 and f(x1) = -0.000516
Required root is: 0.00008602

```

Figure 6. Fixed point method for  $f(x) = xe^{3x^2} - 7x$ .

## Task 5

The routine is given by the following:

```

1 import numpy as np
2
3 def f(x):
4     return x * np.exp(3*np.power(x, 2)) - 7*x
5
6 def bisection(a,b,N):
7     if f(a)*f(b) >= 0:
8         print("Bisection method fails.")
9         return None
10    a_n = a
11    b_n = b
12    for n in range(1, N+1):
13        m_n = (a_n + b_n)/2
14        f_m_n = f(m_n)
15        if f(a_n)*f_m_n < 0:
16            a_n = a_n
17            b_n = m_n
18        elif f(b_n)*f_m_n < 0:
19            a_n = m_n
20            b_n = b_n
21        elif f_m_n == 0:
22            print("Found exact solution:", f_m_n)
23            return m_n
24        else:
25            print("Bisection method fails.")
26            return None
27    return (a_n + b_n)/2
28
29 a = float(input('Guess the first root: '))
30 b = float(input('Guess the second root: '))
31 N = int(input('Maximum steps: '))
32
33 bisection(a, b, N)

```

And the result is given by:

```

[xianggao@Xiangs-MacBook-Pro Tasksheet_04 % python Task_5.py
Guess the first root: -0.5
Guess the second root: 0.5
Maximum steps: 20
('Found exact solution:', 0.0)

```

Figure 7. Bisection method for  $f(x) = xe^{3x^2} - 7x$ .

## Task 6

From this website<sup>1</sup> I found, I realize that root finding methods are important when we can't find a root for a really complicated system, and finding them numerically is sometimes our best shot.

There are also different kinds of shared libraries<sup>2</sup>. For examples:

1. Static Libraires;
2. Global Shared Libraries;
3. Folder-level Shared Libraries;
4. Automatic Shared Libraries

The pro of static libraries is its simplicity, however, you are bounded to program statically (doesn't really know what it means, but it sounds like a con).
